Python Lab Assignment -1

1. Predict the output of the following statements and cross-check your answers using a suitable Python IDE -
 - a. `print(3*2)`
 - b. `print('Hello'*5)`
 - c. `print(3*'Hi')`
 - d. `print('Test','Script')`
 - e. `print('Test',end=' ', 'Script')`
 - f. `print('Test',end='+-','Script')`
2. Write a Python Script to create a variable to hold value 35.5 and print it. Again, assign the value 'This is our test script' and print the value of the variable. Is it possible to assign different types of values to a single variable?
3. Write a Python to accept value of a variable using input(). Test / Try to input an integer value (e. g. 123) and add 1 to the variable. Print the value of the variable.
4. Write a Python Script to create two variables num1 and num2, assign values 10 and 2 one by one respectively. Print the values.
5. Write a Python Script to create two variables num1 and num2, assign values 10 and 2 respectively (in the same line, using multiple initialization). Print the values.
6. Write a Python Script to accept two integers from the user and print their sum.
7. Perform following operations over them, and print the result (with proper messages)-
 - a. sum
 - b. difference
 - c. product
 - d. Division (using /)
 - e. Division (using //)
 - f. Remainder
 - g. Exponent (using **)
8. Is it possible to use a Relational operator greater than (>) to compare two string values? If yes, then what is the criteria (basis) to compare them?

Write the output of the statement - `print('Abc' > 'abc')`.

9. Print the output of the following statements-

- a. `print(not (2>3) and (3>2))`
- b. `print(not ((2>3) and (2>5)))`
- c. `print(not (2>3) or (3>2))`
- d. `print(not ((2>3) or (3>2)))`
- e. `print( (2>3) and not (3>2))`
- f. `print((2>3) or not(3>2))`

10) Execute the following using Python Shell (IDLE) / Jupyter Notebook / Google Colaboratories and write the output-

- a) `print(6 & 3)`
- b) `print(6 | 3)`
- c) `print(~6)`
- d) `print(6<<2)`
- e) `print(6>>2)`

11. Print the output of the following-

`a=5`

- a. `print(a+=1)`
- b. `print(a*=5)`

12. Print the output of the following-

- a. `a, b =10, 10`
 - i. `print(a is b)`
 - ii. `print(a is not b)`

b. `a=10`

`b=a`

- a. `print(a is b)`
- b. `print(a is not b)`

13. Print the output of the following-

- a. `print( 2 in [1,2,2,3,4,5,6])`

- b. `print( 7 in [1,2,2,3,4,5,6])`
- c. `print( 2 not in [1,2,2,3,4,5,6])`
- d. `print( 7 not in [1,2,2,3,4,5,6])`

14. *“Ternary operator (? :) is a valid operator in Python?”* Write your opinion either for or against it.
Execute the following script-

```
print(3>2?"Hello":"Hi")
```

15. Write and execute the following script and analyze the output-

- a. `print('Greater Number = ', (3 if 3>2 else 2))`
- b. `a=int(input('Enter first Integer = '))`
`b=int(input('Enter first Integer = '))`
`print('Greater Number = ', (a if a>b else b))`
